LDA Update Equations

$$P(z_i = j | \mathbf{z}_{-i}, \mathbf{w})$$

$$\propto P(w_i | z_i = j, \mathbf{z}_i, \mathbf{w}_{-i}) P(z_i = j | \mathbf{z}_{-i})$$

$$= \frac{n_{-i,j}^{(w_i)} + \beta}{n_{-i,j}^{(\cdot)} + W\beta} \frac{n_{-i,j} + \alpha}{n_{-i,(\cdot)} + K\alpha} \tag{11}$$

$$= \frac{n_{-i,j}^{(t)} + \beta}{n_{-i,j}^{(\cdot)} + W\beta} \frac{n_{-i,j}^{d_i} + \alpha}{n_{-i,\cdot}^{d_i} + K\alpha} \quad [t = w_i, t \in \{1, \ldots, W\}] \tag{12}$$

$$= \frac{n_{-i,j}^{(t)} + \beta_t}{\sum_{t=1}^{W} n_{-i,j}^{(t)} + \beta_t} \frac{n_{-i,j}^{d_i} + \alpha}{\sum_{k=1}^{K} n_{-i,k}^{d_i} + \alpha_k} \quad [\text{Considering asymmetric parameter for Dir}] \tag{13}$$

$$\tag{14}$$

$n_{-i,j}^{(\cdot)}$ is total number of words assigned to topic j not including current one(i^{th} word).

$n_{-i,j}^{(wi)}$ is the number of instances of word w_i assigned to topic j

β is the hyperparameter that determines Φ

α is the hyperparameter that determine Θ

Sum in the denominator is taken as we need to consider all parameter and the numerator gives the weight of current word to be in the given topic (in first term) and in second term gives the probability of prior(given our experience).

CODE FOR GIBBS SAMPLER

```
/**
 * This demonstrates the nature of Gibbs sampling, namely some pop and push action on a stack (of counting variables).
 *
 * @class_param z[][]
 *    id of topic for document index "m" and word index "n", called the "topic assignment" variable
 * @class_param nw[][]
 *    frequency of word "w" in topic "topic"
 * @class_param nd[][]
 *    frequency of document "m" in topic "topic"
 * @class_param nwsum[]
 *    total number of words in topic "topic"
 * @class_param V
 *    total number of unique words in all topics, called "vocabulary"
 * @class_param K
 *    total number of topics
 *
 * We sample a topic z_i from the full conditional probability distribution:
 *    p(z_i=j | z_\i, w) =
 *       (n_\i, j(w_i) + \beta) / (n_\i, j(.) + V * \beta) *
 *       (n_\i, j(d_i) + \alpha) / (n_\i, .(d_i) + K * \alpha)
 *
 * Here z_\i indicates all z except for z_i.
 *
 * @param m
 *    document, index of the document to sample
 * @param n
 *    word, index of the word to sample (does not need to occur in the document)
 */
```

```cpp
int model::sampling(int m, int n) {
    // remove z_i from the count variables
    int topic = z[m][n];
    int w = ptrndata->docs[m]->words[n];
    nw[w][topic] -= 1;
    nd[m][topic] -= 1;
    nwsum[topic] -= 1;
    ndsum[m] -= 1;

    double Vbeta = V * beta;
    double Kalpha = K * alpha;
    // do multinomial sampling via cumulative method
    for (int k = 0; k < K; k++) {
        p[k] = (nw[w][k] + beta) / (nwsum[k] + Vbeta) *
                    (nd[m][k] + alpha) / (ndsum[m] + Kalpha);
    }
    // cumulate multinomial parameters, sum will be in p[K-1]
    for (int k = 1; k < K; k++) {
        p[k] += p[k - 1];
    }
    // scaled sample because of unnormalized p[]
    double u = ((double)random() / RAND_MAX) * p[K - 1];
```

```
        // get topic with probability beyond u
        for (topic = 0; topic < K; topic++) {
            if (p[topic] > u) {
                break;
            }
        }

        // add newly estimated z_i to count variables
        nw[w][topic] += 1;
        nd[m][topic] += 1;
        nwsum[topic] += 1;
        ndsum[m] += 1;

        return topic;
    }
```

Here we can see the usage of LDA update equation (multinomial sampling via cumulative method)

CODE FOR FORMATTING DATA

```python
import re
from collections import Counter

def get_docs(filepath):
    files = []
    with open(filepath,"r") as f:
        docs = re.split("<TEXT>",f.read())
    for i in docs:
        s = i.split("</TEXT>")
        for j in s:
            if "</DOC>" in j or "<DOCNO>" in j:
                continue
            files.append(j)
    return files
def create_file(files):
    words = []
    with open("formated.txt", "w") as o:
        count = len(files)
        o.write(str(count))
        for f in files:
            words = (re.sub(r'[^\w]', ' ', f).split())
            english_words = map(lambda x:x.lower(), words)
            regex = re.compile(r'\d+(\.\d*)?')
            english_words = filter(lambda i: (not regex.search(i) or i=='.'),english_words)
            eg = Counter(english_words)
```

```
        words_sort = sorted(eg.keys())
        o.write("\n")
        for e in words_sort:
            if len(e) < 3:
                continue
            o.write(e + " ")

a = get_docs("ap.txt")
create_file(a)
```

Result of test data

we are getting similar 10 words which are of same topics. The LDA gibbs sampling works. Increasing number of topics slows down the code but gives results are not good as before. So the data is constant but number of topics are increasing. Therefore as the number of topics increases we could expect the result to be little bad as everything else is same. This could be because the concentration of words to different topics decreases.

Results for number of topics = 20 , 50, 100
